I'm using a lot of Open Source Software and always benefited from the work of the community. So whenever possible I try to contribute and give something back.

As mentioned in other Posts, I'm using SUSE Manager at work, the commercial Product of the Upstream Open Source Project [Uyuni](#), which is a fork of [Spacewalk](#) that [SUSE introduced 2018](#) (Archive: [\[1\]](#), [\[2\]](#)).

So I decided it's time to look for a [good-first-issue](#) and support the Uyuni Project as well. I'm still improving my Java Skills, so I thought some adjustments on the [Setup Bash Script](#) (Archive: [\[1\]](#), [\[2\]](#)) might be the right thing to start with.

The Task was to get the product name from a default config file and use this value instead the hardcoded occurrences of **SUSE Manager** for user visible output.

Today my [pull request](#) (Archive: [\[1\]](#), [\[2\]](#)) was accepted and merged in the Main branch :)
